try finding a few monitor calibration software apps.. and try a few different color profile drivers for windows.. Adobe also has a gamma loader that you "should" run, if you're using Photoshop.. Another issue that could be causing a problem is 32 bit color.. If you pick just the right color, it can look completely different in your image editing program than it does in IE.. and it can look 100 times different on someone elses monitor.

If nothing at all helps, you may have simply come to the end of the life for your monitor.. Is it only purple after it warms up, etc? or right when you turn it on. When you boot windows, is the blackpoint really light and grey, until windows loads its own drivers and splash screen, then it turns darker black?
