I'm on one of these cards as well. It was a damn good budget card when it came out and it's been a decent card throughout the last several years. But in today's gaming age it is utterly useless. You've come to a point in technology where you will absolutely need to upgrade to PCI-E x16 in order to physically play any of the games that came out as early as Doom 3. Now mind you if this is for school or something then go ahead because that card will be fine for general processing. But if you want to game--even with renegade mind you--you will absolutely need to get something better than the FX5200.

I suggest saving up your money and getting a PCI-E board and a 6000 series card if you're on a budget. But if you're patient, save up and wait for the 8000 series coming out this November.
