---

SgtZillalts a NAT router and was wondering does that have anything to do with my hosting problems.

NAT stands for network address translator (I believe) and is used as followed. I believe it also keeps track of the ips of the specific networks so I knows what network it needs to send the data too.

```
networkC
networkA <[NAT]
networkB
```

You may have specific options in your router concerning the NAT features, check it out.

good luck
