Graphics cards' maximum supported refresh rates for average resolutions are way higher than what any monitor can even attempt to display. There is no way that is a factor. If your card overheats even though it's not overclocked, then the reason is one or more of the following:

- the stock fan isn't very good quality and has degraded over time
- the whole cooling in the case is terrible
- the fan just died
- the card is defective

Graphics cards cost a HUGE fortune, they are designed to be much better than to easily fry if you use something like 85hz (or even 120hz).
