...except a newborn baby takes in and processes terabytes of data every second.

The brain automatically can recognise different objects we look at, as well as distance and colour. We also do the same with hearing, IE: I can tell the difference between the sound of a car and the sound of a factory.

There has yet to be a reliable method to do either programmatically. Although that's not impossible, just extremely difficult. We also have yet to program a computer to learn properly and actually understand the meaning of a word.
