(SSnipe) -BLU3Y3Z- wrote on Mon, 28 June 2010 12:13 Thanks for reply I didnt have a clue what hot for a cpu was, someone told me 48c or something was bad thats why i was like wtf?

Well he is right... For stoneage proccessors

Nowadays 70°C is the temperature you should start to watch your CPU. The max core temperature gets higher over the years

Though a CPU works always best on low temperatures so having a good cooling system is not a wrong idea. (liquid nitrogen/helium ftw )

My older CPU would meltdown at ~80°C but gladly it had a failsafe. I should watch it from 60°C but on 70°C it would shutdown the system and only boot after it was cool(er) again.

But then again i overclocked it to twice the speed it was supposed to run on
