This issue has been an on-going problem since the end of November, start of December.

Whilst gaming, my computer has been shutting down and restarting, no errors, no notifications of it doing so, just sudden restart. When the computer restarts it comes up with the message (what you would usually get if the computer didn't shut down successfully), but doing mundane tasks such as browsing, playing Slender or Minecraft = no issues.

I've checked the inside of my computer and cleared any dust, checked for faulty RAM chips and it still happens.

I'm not sure if the trouble causer is my PSU, as I happened to of forgotten what the watts is and what power requirements my graphics card needs.

My PC specs

Motherboard: ASUS M4A77TD

OS: Windows 7 Ultimate

Graphics: EVGA GTX460

RAM: 8GB DDR3 RAM

Processor: AMD Phenom X4 B55 @ 3.30GHz
