Yeah, they shouldn't give you any problems. If anything it is safer running them underclocked. I bought some generic (unbranded) RAM before to see what it runs like and it did have trouble running at 266 Mhz although it was branded as PC2100 it wasn't stable at that speed.

As you said it is future proof. You can stick it in an Athlon FX board if you decided to upgrade. The XP 3000+ series are dropping in price nearly day to day so even one of them are a good upgrade.
