I have a ok computer, everything in it is 5 or so years old. I only need it to play renegade and Half Life(the first one). The memory, video card, and all that is maxed out!

I want to get the best processor it can have because I figure it will be cheep!

Motherboard is "k7t266 Pro. 2 Ver: 2.0"

So whats the absolute best processor I can get for it?

I dont know what the current processor is but I know its not the best it can have.

PS:W00T 50 DAYS TILL WII!!!!

I'm not 100% sure but "K7t266" makes me think it can only support up to a K7(XP3200 would be the best I think, and those aren't even in production anymore), and 266mhz(PC2100?) RAM. If you want anything even remotely up to date you should probably just get an entirely new computer.

Buy a new motherboard instead of wasting your money.

Makes me glad I bought a K8 motherboard, even if it does have a Sempron64 in it now.

you could at max get yourselfs a AMD Athlon 2400+, but it will be second handed then. I don't know what proc you have now, but I dont expect it to be a good upgrade. You could think about an AM2 Athlon 64 and a cheap motherboard and ram, will set you back like 150-200dollar I guess.
